The Role of Fiscal Policy in Human Development: The Pakistan’s Perspective

SYED AMMAD ALI, HASAN RAZA, and MUHAMMAD UMAIR YOUSUF

INTRODUCTION

Human development considered as the engine of the economic growth as it improves the economy’s strength and increases the standard of living of the people, increases the choices and maximises the welfare of the society that is the prime objective of any government. The development of the human capabilities is also necessary for the sustainable growth, as there are many channels through which human development foster the economic growth. It increases the labour productivity, labour demand, employment and output. On the other hand, human capital also attracts physical capital.\footnote{Several studies exist related to human capital and economic growth where different growth channels are defined [e.g. Mankiw, \textit{et al.} (1992); Barro (2001); Bergheim (2005); Benhabib and Spiegel (1994); Bils and Klenow (2000); Temple (2001) and Abbas (2001)].} Empirically, it is very difficult to have an exact measure of human development and social welfare.

Several proxies used to measure human development, e.g. GNI per capita as a measure of standard of living, Purchasing Power Parity (PPP) criterion to measure the cost of living and to measure the welfare, average year of schooling, school enrolment rate and health expenditures as a percentage of GDP to capture this composite welfare and development indicator. A fair index of Human Development Index (HDI) was developed by United Nations Development Programme in 1990. This index based on the standard of living (natural logarithm of GDP PPP per capita), access to knowledge (adult literacy rate with two-third weighting and the remaining is the gross enrolment ratio) and a healthy life (life expectancy at birth). The value of index varies from 0 to 1, lower the HDI, lesser would be the human development and welfare in the country or vice versa.

Fiscal management plays a vital role in attaining the objective of economic and human development, on the one hand, public expenditure should provide those goods and services, which increase the social welfare, reduces inequality and other obstacle of development. On the other hand, if the public revenue structure is compliance with distribution function it will reduce inequality. Many research studies have established a theoretical relationship between and economic growth and fiscal policy such as, Barro (1990) made an extension in endogenous growth model by including government expenditures and taxation with some empirical support. Other worked in the direction of Barro (1990) and different extension was made in endogenous model under the assumptions that public goods and government expenditures both are productive [Sala-i-Martin (1997); Ghosh-Roy (2004); Cashin (1995); Tsoukis-Miller (2003); Devarajan, \textit{et al.}]}

The effectiveness of fiscal policy in Pakistan has been examined in many studies. Some studies discuss the relative importance of monetary and fiscal policy or crowding out effect while other examined the debt sustainability [Masood and Ahmad (1980); Saqib and Yasmin (1987); Mahmood, et al. (2009); Hassan (1999); Chaudhary and Anwar (2000); Siddiqui and Malik (2001); Jafri (2008) and Hyder (2001)]. In most of these studies, growth effects of fiscal policy was measured, while in some cases role of fiscal policy in poverty eradication and in some studies effects on education. The objective of this study is to analyse the role of fiscal policy in human development and social welfare, which is an ultimate goal of any public policy. This study also examined the effect of government type on human development in Pakistan. The study period consists of 1972 to 2010. Furthermore, the unit root test is applied to check the stationary of the data series. Finally, the autoregressive distributed lags (ARDL) bond testing approach of cointegration is applied to find the long run and short run relationship.

Some Stylised Fact

The value of HDI for Pakistan is 0.504, the country of the low human development category. Its ranking is 145 out of 187 countries [HDR (2011)]. The data analysis based on new variables shows an improving trend in all the variables of Pakistan’s HDI which include GNI PPP per capita (from US$ 1288 to US$ 2550) to measure the standard of living, life expectancy at birth (from 57.9 years to 65.4 years) for a healthy life while expected years of schooling (from 5.7 to 6.9 years) and the mean years of schooling (1.8 to 4.9 years) are used to measure the access to knowledge. The improvement in all the components has improved the overall HDI from 0.359 to 0.504 in the period of 31 years. Table A1 in the Appendix shows the comparative static analysis of Pakistan relative to South Asia and World from 1980 to 2011. The overall improvement in HDI in all the countries and regions of the world is being experienced in this duration. Table A2 demonstrates the values and rank of HDI in Pakistan relative to selected countries (India and Bangladesh) and groups (South Asia and Low HDI) in the year 2011.

Fig.1.Trend of HDI

![Fig.1.Trend of HDI](image-url)
The remaining study is divide as Section 2 based on reviews of previous studies, Section 3 based on methodological framework and data sources, Section 4 illustrates empirical results, and finally Section 5 demonstrates conclusion and policy implication.

2. REVIEW OF LITERATURE

The increasing literature, theoretical as well as empirical, on the impact of the role of the public expenditure on the welfare and wellbeing of the people is not representing the comprehensible picture and the results are ambiguous. Some researchers found positive impact of public expenditure and role of the size of the government on the welfare but some show negative. Davies (2009) analysed the impact of government size on HDI and tried to find an optimal level of government size with respect to human development instead of GDP growth, as usually does, by using a panel data set of 154 countries from 1975 to 2002 through a GMM technique and found that the welfare maximising size of government (government consumption to GDP ratio) is 17 percent. Iganiga (2012) empirically investigated the impact of different government expenditure on welfare of the Nigerian economy, the government expenditures consist on total federal government revenue, recurrent administrative expenditure, capital administrative expenditure, and federal education expenditure, dummy for political regime and Human Development Index for welfare measure. Using a quarterly data from 1990 to 2009 and concluded that the government having the minimum administrative cost conditional with the reliable people and self-motivated policies can be helpful to reduce poverty on one side and might improve health and productivity that would directly or indirectly improve the living standard of the Nigerian people.

Devereux, et al. (2000) searched the channel of government spending on the consumption and welfare. The effect on the total productivity of the economy showed that private consumption and welfare was inversely related with government spending in the case of constant returns while positively related in the case of increasing returns to specialisation. Armey (1995) portrays the relationship between the government size (federal spending as percentage of GDP) and the economic growth (the real GDP) of the economy as the inverted U-shaped Armey curve. Smith and Wahba (1995) analysed the role of public revenue and expenditure of the government on the economic development of 56 developing countries. Among different model, they also examined the effect of fiscal policy on human development by using human development index as dependent variable and social and community expenditures, expenditures on economic services, infrastructure, defense, foreign aid, direct and indirect taxes, labour growth, export growth and gross domestic investment as explanatory variables. The result shows that investment; infrastructure, direct taxes and social expenses have a positive effect on HDI.

Public expenditures on basic public goods, like law and order and other social aspects, have positive impact on the economic growth until a certain limit, that varies from country to country depending upon the political and structural organisation, while additional and non-productive increase in the public expenditures have a negative effect on the economic growth and other social indicators. Vedder and Gallaway (1998) analysed the optimal size of the government for the US economy from 1947 to 1997. Kefela and Rena (2007) examined human capital as the engine of economic growth in North East African States because of investment in human capital, which was the result
of increase in the GDP per capita. Yavas (1998) analysed the link between the
government size per capita output and the growth rate for LDCs and the developed
countries. The increase in the government size for the developing countries would boost
the steady state output level when there is low steady state of the economy, but for the
developed countries, it would decrease the steady state output level at a high steady state.

Some other studies show inverse relationship between the federal expenditure and
the welfare of the people. The foundation of the economic growth is human development
but it is not necessary for all the countries to get benefits of this economic growth in the
form of the human development because the accumulation of the productive knowledge
and expertise is the real development for the country. The educated and productive public
is the goal of development, which will also result in the eradication of poverty. Heitger
(2001) examined 21 OECD countries and found negative link between the government
expenditure and the economic growth from 1960 to 2000.

Amakom (2010) suggested that expenditure in the improvement of literacy rate
and providing better health facilities could help to eradicate poverty in the economy by
using the welfare dominance test. He concluded that primary education was progressive
for male and female in Nigeria. By employing quintile regressions, Gomanee, et al.
(2003) studied the effect of the aid on the welfare in terms of HDI. The negative link
between poverty alleviation and aid, depend upon the higher HDI. Suescún (2007)
investigated the case for 15 Latin American economies. In his dynamic general
equilibrium model, different public expenditures were used. The investment in the
infrastructure took over education, health, government consumption and transfers, which
are the other sources of public spending to have positive impact on the human
development and welfare of the people. Machicado, et al. (2008) employed Dynamic
Stochastic General Equilibrium Model to analyse the link between investment in
infrastructure, health and education with respect to the welfare of the Bolivian economy.
Forte and Magazzino (2010) examined the shape of the BARS curve to find out the
relationship between the size of the government and the economic growth. The panel data
set used for the 27 EU countries ranging from 1970 to 2009 showed that for EU-27, the
crest of the BARS curve is at 37 percent but its actual level is about 47 percent.

Abbas (2000) compared the role of human capital in economic growth and role of
human capital in physical capital accumulation between India and Pakistan. The study
period consists of 1970 to 1994 and the estimation technique based on an ordinary least
square method. Human capital was measured through three different proxies; primary,
secondary and high school enrolments are used. He also generated a variable of effective
labour input by combining the different school enrolment and employment rate and
measured the impact on economic growth of this variable. The results evident that in
growth accounting with human capital as factor of production, primary school enrolment
has positive impact on growth for India only, while secondary enrolment has positive
effect for both countries and higher school enrolment has positive effect just only for
Pakistan. The results of second part of the study, which are related to the impact of
human capital and effective labour on physical capital accumulation, evident that school
enrolments have no significant impact on physical capital accumulation for both
countries but effective labour has a significant impact on physical capital accumulation
for both countries.
Qadri and Waheed (2011) analysed the role of human capital in economic growth of Pakistan by using annual data from 1978 to 2007 through Johansen cointegration technique. A health adjusted education indicator is used, as a proxy for human development; they found a strong positive effect of human capital on economic growth. Mahmood and Sara (2010) examined the impact of fiscal decentralisation on human development using human development index as dependent variable in case of Pakistan. The study period consist of 1976-2009 while two different models were used; in the first model, a cointergration is applied and established a long run relation and in second step, they measured the affect of decentralisation on human development at provincial level using panel GMM; the results show that decentralisation increases the human development. Asghar, et al. (2011) analysed the impact of public spending on poverty reduction in Pakistan by using a data set from 1972-2008 through a VECM model. The model based on head count index, used as a proxy of poverty, as a dependent variable, public health, education, law and order, economics and community services as a percentage of GDP and budget deficit used as explanatory variables. They found that government spending on education, law and order reduce the poverty level while spending on community services, and budget deficit have positive impact on poverty, but health expenditure have no significant effect on poverty.

3. METHODOLOGICAL FRAMEWORK AND DATA SOURCES

3.1. Data Sources

This study employs time series data of different macroeconomic variables for Pakistan having the span from 1972 to 2010 which are available from different secondary sources. The publications of the World Bank (World Development Indicators; WDI), United Nation Reports and several issues of the Economic Survey of Pakistan are employed for the quantitative data of Human Development Index (HDI), log of real per capita income (LRPCI), log of real current expenditure (LRCUREXP)
, log of real development expenditures (LRDEVEXP), log of real tax revenue (LRTR), log of real expenditure on education (LREDU) and a dummy for political regime in Pakistan (PR): 1 for democracy and 0 for dictatorship.

3.2. Econometric Model and Technique

For measuring the role of fiscal policy in human development a linear regression model is formulated which has the following functional form:

\[ HDI_t = \alpha_0 + \alpha_1 LRPCI_t + \alpha_2 LRCUREXP_t + \alpha_3 LRDEVEXP_t + \alpha_4 LRTR_t + \alpha_5 LREDU_t + \alpha_6 PR_t + \epsilon_t \]

\[ \text{(1)} \]

Unit Root Analysis

Stationary is a vital issue in time series data and Augmented Dickey-Fuller (ADF)
 test is applied to find the order of integration among the variables under the null hypothesis of unit root.

\(^2\text{Current expenditure consists on federal government revenue, budget’s non-development expenditure i.e. general administration, defense, law and order, community services, social services and economics services.}\)

\(^3\text{Development expenditure is the capital and revenue budgets’ development expenditures.}\)

\(^4\text{For detail see Dickey and Fuller (1979).}\)
Cointegration Analysis

There are many econometric approaches exist to find the long run relationship among the variables. The pioneer work of Engle-Granger (1987), some other famous studies are based on maximum likelihood procedure Johansen (1991, 1992), and Johansen and Juselius (1990). Another techniques introduced by Pesaran and Shin (1995, 1999), Pesaran, et al. (1996) and Pesaran (1997) which is autoregressive distributed lags (ARDL) Model. This procedure has many advantages over the old methods, such as, the order of integration does not matter here similarly old methods were better for large sample while it’s also effective for small sample even different variables have different lags. Due to these superiorities, we applied an ARDL bond testing approach to cointegration which is better suited to small samples [Haug(2002)]. An ARDL representation of Equation (1) can be formulated as

\[ \Delta HDI_t = \kappa_0 + \pi PR_t + \sum_{i=0}^{K_1} \delta_i \Delta RPCI_{t-i} + \sum_{i=0}^{K_2} \beta_i \Delta LRCUR\text{EXP}_{t-i} + \sum_{i=0}^{K_3} \omega_i \Delta LRDEV\text{EXP}_{t-i} + \sum_{i=0}^{K_4} \eta_i \Delta LRTR_{t-i} + \sum_{i=0}^{K_5} \theta_i \Delta REDU_{t-i} + \sum_{i=0}^{K_6} \phi_i \Delta HDI_{t-i} + \lambda_0 LRPCI_{t-1} + \lambda_1 LRCUR\text{EXP}_{t-1} + \lambda_2 LRDEV\text{EXP}_{t-1} + \lambda_3 LRTR_{t-1} + \lambda_4 REDU_{t-1} + \lambda_5 HDI_{t-1} + v_t \ldots \ldots (2) \]

The Equation (2) is used to find cointegration among the variables defined in Equation (1), here \( K_1, K_2 \ldots K_6 \) are the showing the optimal lag length determined by information criterion and \( \Delta \) is the first-difference operator. A bond testing approach of Pesaran, et al. (2001) is applied to find the long run relationship. This methodology based on \( F \) or Wald-statistics, a joint significance test under the null hypothesis of no cointegration \( H_0: \lambda_0 = \lambda_1 = \lambda_2 = \lambda_3 = \lambda_4 = \lambda_5 = 0 \) against the alternative hypothesis \( H_1: \lambda_0 \neq \lambda_1 \neq \lambda_2 \neq \lambda_3 \neq \lambda_4 \neq \lambda_5 \neq 0 \) is tested. This F-test has a non-standard distribution and two sets of critical values: one is lower bond for \( I(0) \) and other is upper bond for \( I(1) \). The decision of cointegration based on these values; if the calculated F-Test value exceeds the upper bond then \( H_0 \) is rejected. If the F-Test statistics are lower than the lower limit, \( H_0 \) cannot be rejected and if the F-Test statistics lie between the lower and upper bond limits, the test is inconclusive.

After the confirmation of cointegration among the variables an error correction model is formulated from the Equation (2)

\[ \Delta HDI_t = \kappa_0 + \pi PR_t + \sum_{i=0}^{K_1} \delta_i \Delta RPCI_{t-i} + \sum_{i=0}^{K_2} \beta_i \Delta LRCUR\text{EXP}_{t-i} + \sum_{i=0}^{K_3} \omega_i \Delta LRDEV\text{EXP}_{t-i} + \sum_{i=0}^{K_4} \eta_i \Delta LRTR_{t-i} + \sum_{i=0}^{K_5} \theta_i \Delta REDU_{t-i} + \sum_{i=0}^{K_6} \phi_i \Delta HDI_{t-i} + \lambda_5 ECM_{t-1} + v_t \ldots \ldots (3) \]

Where ECM is the error correction term and \( \lambda_5 \) is the speed of adjustment. All the equations are analysed through econometric analysis package Microfit.
4. EMPIRICAL RESULTS

In ARDL model, no pre-testing is required to determine the order of integration but any higher order of integration may cause unreliable results [Ouattara (2004)]. To make sure that the order of integration is lower than the I(2) ADF test is applied. The results of unit root test are shown in Table 2, where all the series are non-stationary at level but stationary at first-difference, that is, the series are I(1) stationary.

Equation (2) is used for cointegration by using initially 4 lags as suggested by AIC and BIC. The ARDL method run a total \((4+1)^6 = 15625\) regressions and finally on the basis of AIC criterion an ARDL(2,1,4,4,3,4) is selected. A variable deletion test is applied to calculate the F-statistics. Table 3 shows the calculated value with Narayan critical bond values; the calculated F-value exceeds the upper bond limit and indicates the existence of cointegration.

*Note: Based on Narayan (2004) Table Case. ii.

After the confirmation of cointegration, the long run impact of fiscal policy on human development is reported in Table 4. The results show that real per capita income has a significant positive effect on human development and it is the highest determinant of human development as the economic theory suggests; the coefficient of real per capital income shows that a one percent increase in per capita income will increase human development by 0.1 units.

D: Based on the regression of squared residuals on squared fitted values.

Government current expenditures are insignificant but have a negative effect on human development; government development expenditure have a significant positive effect on human development and the coefficient suggests that an increase of one percent in development expenditure will increase human development by 0.06 unit. Taxes have a negative though insignificant effect on human development, the plausible reason of this negativity is, in Pakistan the distribution of taxes are very uneven and tax policy has a heavy reliance on indirect taxes which usually create distortion and hit the consumer badly. Education expenditure has significantly positive effect on human development. The coefficient of education expenditures shows that a one percent increase in education expenditure will increase the human development by 0.06 units. More interestingly, the type of government based on a dummy variable, PR is significant and showing that democratic governments have a negative effect on human development while the dictatorship increases the human development.

The results of error correction model or short run behaviour of human development with respect to fiscal policy are generated from Equation (3) and presented in Table 5. The variable ECM is showing the short run adjustment in the human development due to change in exogenous variables, the coefficient of ECM (–1) is –0.2838 which is highly significant also confirming the existence of cointegration and it shows that a deviation from equilibrium during the current year will be corrected by 28.38 percent in the next period.

Furthermore the lower part of Table 4 consists of diagnostic tests shows that model is well fitted a high R², while the LM test for serial correlation indicate no serial correlation. Ramsey’s RESET shows that functional form is correct. Normality test also confirms the normal distribution and the heteroscedasticity test also in the favour shows no heteroscedasticity. Finally for parameter’s stability, a cumulative sum and cumulative sum square tests have been applied as recommended by Pesaran and Shin (1999). The graphs of both tests are presented in Appendix B; Figure 1 and Figure 2. Both graphs depict that CUSUM and CUSUMSQ lie within 5 percent significance boundaries, which indicate that both short-run and long-run parameters are stable as proposed by Brown, et al. (1975).

### 5. CONCLUSION AND POLICY IMPLICATIONS

Economic development is the ultimate goal of every government and a renowned criterion for measuring the development is HDI. Higher the value of HDI, higher is the human development level. In this study, we explore one of the major government policy i.e. fiscal policy role in human development, not only this, we also examined the role of government type (democratic/dictatorship) in human development.
The results show that per capita income level should be increased to increase the human development level as this is the major determinant of HDI. Current expenditure has insignificantly negative effect on human development in short run. This negative effect raises the questions related to current expenditures because these expenditures mainly consist of general administration, defence, law and order, community services, social services and economics services; which are also necessary for economic development. But this negative sign emphasises to increase the efficiency of government institutions, while development expenditures are showing a satisfactory situation empirically because they have significant positive effect. Tax revenue has a negative sign but statistically insignificant which is indicating that tax policy have no development effect, which is certainly not a good sign. Education expenditure has significantly positive effect on human development; as other studies also found and this finding also strongly recommends to the policy makers to increase the education expenditure share which is hardly 2 percent of GDP (including current education expenditures). Finally political regime concludes that democratic governments have a negative effect on human development.
